The science of storytelling: the David Attenborough style of scientific presentation

William C. Ratcliff  

Published: July 19, 2023 • DOI: <https://doi.org/10.1016/j.molmed.2023.05.002>

Abstract

Many scientists approach speaking as they do writing a paper: an opportunity to present their data. But data without proper context is difficult to absorb. In this article, I describe a philosophy and set of heuristics for giving an engaging, narratively driven talk, inspired by the legendary documentaries of Sir David Attenborough.

Abstract

Evolutionary transitions in individuality are central to the emergence of biological complexity. Recent experiments provide glimpses of processes underpinning the transition from single cells to multicellular life and draw attention to the critical role of ecology. Here, we emphasize this ecological dimension and argue that its current absence from theoretical frameworks hampers development of general explanatory solutions. Using mechanistic mathematical models, we show how a minimal ecological structure comprising patchily distributed resources and between-patch dispersal can scaffold Darwinian-like properties on collectives of cells. This scaffolding causes cells to participate directly in the process of evolution by natural selection as if they were members of multicellular collectives, with collectives participating in a death–birth process arising from the interplay between the timing of dispersal events and the rate of resource use by cells. When this timescale is sufficiently long and new collectives are founded by single cells, collectives experience conditions that favour evolution of a reproductive division of labour. Together our simple model makes explicit key events in the major evolutionary transition to multicellularity. It also makes predictions concerning the life history of certain pathogens and serves as an ecological recipe for experimental realization of evolutionary transitions.

Cover letter

We are pleased to submit our paper "Topological constraints in the origins of reproductive specialization" to be considered for publication in *eLife*.

Reproductive specialization (e.g., cellular differentiation into germ and somatic cells) is a hallmark of complex multicellular organisms. Specialization is thought to evolve due to trade-offs in a cell's ability to both reproduce and to aid in the survival of the organism. Reproductive specialization is of central importance to multicellularity – it not only facilitates the evolution of organismal complexity by mitigating conflicts between cellular and multicellular fitness, but it is also the primary route through which multicellular organisms evolve novel, more complex traits.

A large body of literature, from evolutionary game theory to economic bargaining theory, has shown that complete reproductive specialization should only evolve when the payoff from differentiation accelerates with increased specialization. Indeed, this is considered a fundamental constraint on the evolution of any kind of specialization. In this paper, we show that germ-soma differentiation is different from other forms of biological specialization, and as a result, can evolve under a much broader set of conditions, including conditions without accelerating payoffs.

First, we investigate the potential for emergent reproductive specialization to evolve in simple multicellular organisms, modeled as networks of connected, interacting cells. Through a combination of graph theoretic analysis and evolutionary dynamic modeling, we analyze the extent to which specialization can emerge between cells in a network, insofar as selection acts at the scale of the multicellular organism as a whole. We show that the fundamental asymmetry of exchange rules (i.e., a cell cannot share the ability to reproduce, but it can help other cells survive) and different evolutionary optima for multicellular fitness vs. the fitness of component cells, allow reproductive specialization to evolve even when the returns from specialization decelerate with greater investment in trade. This is a major conceptual advance in our understanding of how reproductive specialization can evolve, overturning decades of prior theory.

Second, we show that the cellular topology of multicellular organisms plays a key role in either promoting or constraining the evolution of reproductive specialization. We find that specialization is strongly promoted in simple multicellular organisms that grow with permanent cell-cell bonds, forming tree-like topologies. Such topologies appear to be ancestral to nearly all eukaryotic lineages that ultimately evolved complex multicellularity (i.e., large size, multiple cell types, and complete reproductive specialization), and readily arises in laboratory models of early multicellularity. We identified the topology of two representative early multicellular organisms: a billion-year-old fossilized red alga, *Bangiomorpha* and snowflake yeast, a laboratory model system of early multicellularity, and then used these topologies to parameterize evolutionary models. The topology of both organisms strongly promotes the emergence of reproductive specialization in our evolutionary dynamic framework.

Our work combines theory, numerical simulations, and image-based topological analyses of early multicellular organisms. Our focus on network topology provides unique insight into the origin of reproductive specialization in multicellular organisms: a critical step for the evolution of complex life on Earth. We anticipate that this paper will be of broad interest to a wide range of *eLife* readers, including those with an interest in evolutionary biology, cellular biology, computational biology, developmental biology, and the physics of living systems.

This manuscript contains 4252 words in the main text, with one table and four main figures composed of 16 sub-panels. The supplementary information section contains 1400 words including figure captions, one table, and two supplemental figures totaling five panels. None of the submitted material has been published or is under consideration elsewhere. We do not have any related papers in press or under consideration.

Please do not hesitate to contact us if you have any questions.

Sincerely,

Peter J. Yunker, Assistant Professor, School of Physics, Georgia Institute of Technology
William C. Ratcliff, Associate Professor, School of Biology, Georgia Institute of Technology

Whole paper

Introduction

First PP big picture context

Then zoom in on topic. Say what is known on this topic, and what the gap is (2-4 PPs). If you have room, explain why this gap persists and how your research circumvents this gap.

Say what you did (last PP)

Results

Say what you did. The story should be understandable from the figures, so make them first and use them to lay out the progression.

Discussion

Reprise big picture context for paper (first few sentences of first PP)

Restate major results (second part of first PP)

Explain how your results fit in with the broader literature. How do your results change the way we think about the knowledge gap, big picture topic, and/or methods? What are key next steps? Limitations? End with a clear restatement of how this work changes the way we think about the big picture topic.

Methods

Easy-say what you did.
